# **Exercises: Simple Gaussian Linear Model**

### Exercise 1, exam 24/09/2024

A person's muscle mass is expected to decrease with age. To explore this relationship in women, a nutritionist randomly selected four women from each 10-year age group, beginning at age 40 and ending at age 79, and recorded their muscle mass index.

The observed values of age (x) and muscle mass (y) are:

| unit           | 1  | 2  | 3   | 4  | 5  | 6   | 7   | 8  |
|----------------|----|----|-----|----|----|-----|-----|----|
| $\overline{x}$ | 71 | 64 | 43  | 67 | 56 | 73  | 68  | 56 |
| y              | 82 | 91 | 100 | 68 | 87 | 73  | 78  | 80 |
|                |    |    |     |    |    |     |     |    |
| unit           | 9  | 10 | 11  | 12 | 13 | 14  | 15  | 16 |
| $\overline{x}$ | 76 | 65 | 45  | 58 | 45 | 53  | 49  | 78 |
| y              | 65 | 84 | 116 | 76 | 97 | 100 | 105 | 77 |

Moreover, it is known that

$$\sum_{i=1}^{16} x_i = 967 \qquad \sum_{i=1}^{16} y_i = 1379$$

$$s_x^2 = 131.0625 \qquad s_y^2 = 202.2958 \qquad s_{xy} = \frac{1}{15} \sum_{i=1}^{16} (x_i - \bar{x})(y_i - \bar{y}) = -134.1542$$

where  $s_x^2$  and  $s_y^2$  are the unbiased estimates of the sample variances of x and y, respectively; and  $\bar{x}$  and  $\bar{y}$  are the sample means.

Assume that the following Gaussian linear model is appropriate:

Model A: 
$$Y_i = \beta_1 + \beta_2 x_i + \varepsilon_i$$
,  $\varepsilon_i \stackrel{iid}{\sim} N(0, \sigma^2)$ .

The estimates of the variances of the estimators are

$$v\hat{a}r(\hat{\beta}_1) = 133.63$$
  $v\hat{a}r(\hat{\beta}_2) = 0.03542$ 

while the unbiased estimate of the variance  $\sigma^2$  is

$$s^2 = 69.62.$$

Answer the following questions:

- a) Write the expression of the estimated regression function.
- b) Derive and explain the interpretation of the coefficient associated with the age variable.
- c) Perform a statistical test to test the hypothesis  $H_0: \beta_2 = 0$  against the alternative  $H_1: \beta_2 < 0$ .
- d) Derive a 95% confidence interval of the age coefficient. Can you say anything about the significance of the coefficient?
- e) Two new women "A" and "B" enter the study. Woman A is 38 while woman B is 60 years old. What is their predicted muscle mass according to the fitted model? What prediction has the largest uncertainty? Why?
- f) Provide the definition of residuals. Obtain the value of the residual for the 8th observation. What is the value of the sum of the residuals for the specified model? Explain why.
- g) Obtain the coefficient of determination  $\mathbb{R}^2$  and interpret it.

#### Exercise 2: Mother and Daughter heights data

Let us consider a sample of n = 11 observations of two variables (Table 1):

- mother's height  $x_i$ , i = 1, ..., n (independent variable);
- daughter's height  $y_i$ , i = 1, ..., n (dependent variable).

Table 1: Mother and Daughter heights data: data are expressed in centimeters.

|                | 1     | 2     | 3     | 4     | 5     | 6     | 7     | 8     | 9     | 10    | 11    |
|----------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| $\overline{x}$ | 153.7 | 156.7 | 173.5 | 157.0 | 161.8 | 140.7 | 179.8 | 150.9 | 154.4 | 162.3 | 166.6 |
| y              | 163.1 | 159.5 | 169.4 | 158.0 | 164.3 | 150.0 | 170.3 | 158.9 | 161.5 | 160.8 | 160.6 |

We want to study the relationship between the two variables. Answer the following:

- (a) Starting from the data in Table 1, write the equation of the Gaussian simple linear regression model and the associated assumptions.
- (b) Knowing that

$$\bar{x} = 159.76, \qquad \bar{y} = 161.49, \qquad \sum_{i=1}^{n} x_i^2 = 281940.6$$

$$\sum_{i=1}^{n} y_i^2 = 287179.3, \qquad \sum_{i=1}^{n} x_i y_i = 284335.1,$$

compute the maximum likelihood estimates  $(\hat{\beta}_1, \hat{\beta}_2)$ 

- (c) Compute the unbiased estimate of the variance  $s^2$ .
- (d) Perform a statistical test to test the following system of hypothesis

$$\begin{cases} H_0: \beta_2 = 1 \\ H_1: \beta_2 \neq 1 \end{cases}$$

- (e) Obtain the confidence intervals for  $\beta_r, r = 1, 2$  using a confidence level  $1 \alpha = 0.95$ .
- (f) Compute the total sum of squares (SST), the residual sum of squares (SSE) and the regression sum of squares (SSR). Then, find the coefficient of determination  $R^2$ . Compute the correlation coefficient  $\rho_{X,Y}$  and its squared. What happens in this case?
- (g) Perform a statistical test to test the following system of hypothesis

$$\begin{cases} H_0: R^2 = 0 \\ H_1: R^2 > 0 \end{cases}$$

and compute the p-value. In the model under study, is there an equivalent test? Specify the set of hypotheses and the test statistic. What is the p-value following this procedure?

(h) We have seen the equivalence between the test about the significance of  $\beta_2$  and the test about  $R^2$  in the simple linear model. Provide the formula and verify that it holds with the data.

2

#### **Exercise 3: Computer repair data**

A computer repair company is interested in understanding the relationship between the number of electronic components to repair and the duration of the intervention (in minutes). Therefore, a simple linear regression model was fitted to study the duration (y) as a function of the number of repaired units (x).

A sample of n = 14 interventions provided the following data:

$$\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i = 95.768, \qquad \bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i = 6,$$

$$\sum_{i=1}^{14} (y_i - \bar{y})^2 = 31108.357, \qquad \sum_{i=1}^{14} (x_i - \bar{x})^2 = 114$$

Moreover, the fitted model provides a coefficient of determination  $R^2 = 0.984$ .

- (a) Compute the maximum likelihood estimates of  $\beta_1$  and  $\beta_2$ . Then, write the equation of the estimated regression line.
- (b) Find the estimate of the variance  $\sigma^2$  using the decomposition of the total sum of squares. Through an adequate test, test the significance of the overall model using a 5% significance level.
- (c) The estimates of the standard errors of the estimators  $(\hat{B}_1, \hat{B}_2)$  are

$$\sqrt{\widehat{Var}(\hat{B}_1)} = 4.014, \qquad \sqrt{\widehat{Var}(\hat{B}_2)} = 0.604.$$

Through a valid test (using a 5% significance level), verify whether the coefficients  $\beta_1$  and  $\beta_2$  are significant.

(d) Is there any statistical test performed in (c) that was unnecessary, given the results of (a) and (b)?

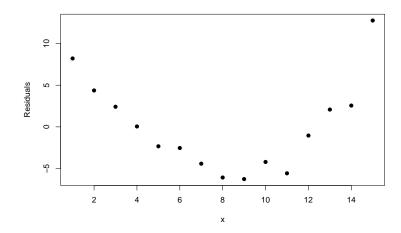

## Exercise 4: Bacteria mortality data

Suppose we want to analyze bacterial mortality (y) as a function of radiation exposure (x). The output of fitting a Gaussian linear regression model of y as a function of x is partially summarized in the table below:

|             | Estimate | Std. Error | t value | p-value  |
|-------------|----------|------------|---------|----------|
| (Intercept) | 49.162   | 22.76      | ?       | ?        |
| Exposure    | -19.46   | ?          | -7.79   | < 0.0001 |

Moreover, it is known that n = 15,  $R^2 = 0.823$  and s = 41.83.

- (a) Complete the missing values in the table.
- (b) Through a valid statistical test, evaluate the significance of the overall model.
- (c) Given the following plot of the residuals against x, what can you say about the model assumptions? Were they reasonable?

|                  | p      |        |        |        |        |        |        |  |
|------------------|--------|--------|--------|--------|--------|--------|--------|--|
|                  | 0.90   | 0.95   | 0.975  | 0.99   | 0.995  | 0.9975 | 0.999  |  |
| $\overline{z_p}$ | 1.2816 | 1.6449 | 1.9600 | 2.3263 | 2.5758 | 2.8070 | 3.0902 |  |

Table 2: Some quantiles of the Gaussian distribution:  $p = \mathbb{P}(Z \leq z_p)$ . Columns correspond to probabilities p.

|            | 0.9    | 0.95   | 0.975   | 0.99    | 0.995   | 0.9975   | 0.999    |
