Gaussian simple unbar retression

Assume that on n statistical units we observe (yi, xi), i=1,..., n.

We assume that each yi is realization of a random voriable Yi, and that Yzi...i'm are independent.

We only consider one convoice Xi, i=1,..., n.

Consider the model

HYPOTHESES:

1. E[&]=0 i=1,...,n

2. $Vor(Ei) = 6^2$ for all i=1,...,n hyp. from last time

3. cor(&; &k) = 0 i + K; i, K=4..., w + 4. Ei have Gaussian distribution

Yi= P1 + P2 xi + & i= 1,..., n

Recall that for a normal r.v. corr = 0 => independence

⇒ & N(0,62) i=4,..., n

Since now we have distributive assumptions, we can derive the estimators

⇒ Yi ~ N(B1+B2xi, 62) independent (but not identically distributed)
