Consider the model Yi = \$1 + \$2 xi2 + ... + \$ xi8 + \$2 xi3 + ... + \$ xi6 + 6: €: ~ N(0, 6²) WE WORD TO DEST joiNDLY (PR+1,..., Pp) = 0

(Ho: Por = ... = Po = 0 [Ha; Ho; at east one of them is to (3re fpo+1,...,p): Pr to)

idea:

under Hz, I have p coveriences (we call it the "full model") I can extinct this model, obtaining $\hat{\beta}$, and compute the residuals $\underline{c} = \underline{y} - \underline{x}\hat{\beta}$

then, I compute the sum of the squared residuals = ==

under the 1 house the model Yi = \$1 + \$2 xiz + ... + \$10 xis + & -> \$6 coveriences I am constraining the coefficients (BB+1,..., B) to be = 0 (we call it the "restricted model")

I can estimate this model, obtaining $\tilde{\beta}$, and I obtain the residuals $\tilde{\underline{c}} = \underline{y} - \tilde{\underline{y}}$

The sum of squared residuals is ere

We know that <u>ete ≥ ete</u>, wince the model under the is a conftrained version of the full model. In particular, the difference between the two will be large if the coefficients that I have forced to zero one actually relevant for the analysis.

Notice that the two models are NESTED; meaning that the model under Ho is included into the model under H1 (it can be obtained from the full model using a set of constraints). Coreful: if the models one not nexted you can not use the text to compone them.

How we Dest the hypotesis:

It is useful to write the model in a way to highlight the separation between the unconstrained

parameters and the ones we are testing. Write

$$\frac{\beta}{\beta_{1}} = \begin{bmatrix} \beta_{1} \\ \beta_{2} \\ \vdots \\ \beta_{p} \end{bmatrix} = \begin{bmatrix} \beta^{(0)} \\ \beta^{(1)} \end{bmatrix} \qquad \frac{\beta^{(0)} \in \mathbb{R}^{p_{0}}}{\beta^{(1)}} = \frac{\beta^{(1)} \in \mathbb{R}^{p_{0}}}{\beta^{(1)}} = \frac{\beta^{(1)} + \beta^{(1)}}{\beta^{(1)}} = \frac{\beta^{(1)} +$$

Similarly, we partition the matrix X into 2 sub-matrices

$$X = \begin{bmatrix} x_{11} & x_{12} & \dots & x_{1p} & x_{1}, p_{0+1} & \dots & x_{1p} \\ \vdots & \vdots & & \vdots & & \vdots \\ x_{n1} & x_{n2} & \dots & x_{np} & x_{n_1} p_{0+1} & \dots & x_{np} \end{bmatrix} = \begin{bmatrix} x^{(0)} & x^{(1)} \\ x^{(1)} & x^{(1)} \end{bmatrix}$$

Hence we obtain

FULL HODEL (H₁)
$$\underline{Y} \sim N_{n} (X_{1}^{B}, \sigma^{2} \underline{\Gamma})$$

$$\underline{Y} = X_{1}^{B} + \underline{\varepsilon} = \left[X^{(o)} X^{(v)} \right] \left[\frac{\beta^{(o)}}{\beta^{(v)}} \right] + \underline{\varepsilon}$$

$$= X^{(o)} \underline{\beta}^{(o)} + X^{(d)} \underline{\beta}^{(d)} + \underline{\varepsilon}$$

$$\frac{\hat{\beta}}{\underline{\beta}^{(v)}} = (X^{(v)^{T}} X^{(v)})^{-1} X^{T} \underline{\beta}$$

$$\underline{\hat{\beta}^{(o)}} = (X^{(o)^{T}} X^{(o)})^{-1} X^{(o)^{T}} \underline{\beta}^{(o)}$$

$$\underline{\hat{\beta}^{(o)}} = (X^{(o)^{T}} X^{(o)})^{-1} X^{(o)^{T}} \underline{\beta}^{(o)}$$

If Ho is thue, removing $\underline{\beta}^{(4)}$ in the model will not make a big difference for predicting y. If Ho is not true, removing $B^{(1)}$ wice each to worse results (earger errors).

under Ho, l'expect ETE & ETE

⇒ ere ≈ 1 ⇒
$$\frac{62}{62}$$
 ≈ 1

To perform the test, we one gaing to use again a function of $\frac{62}{22}-1$

 $\Rightarrow \frac{\tilde{c}^{T}\tilde{c}}{\tilde{c}^{T}} \gg 1 \Rightarrow \frac{\tilde{c}^{2}}{\tilde{c}^{2}} \gg 1$

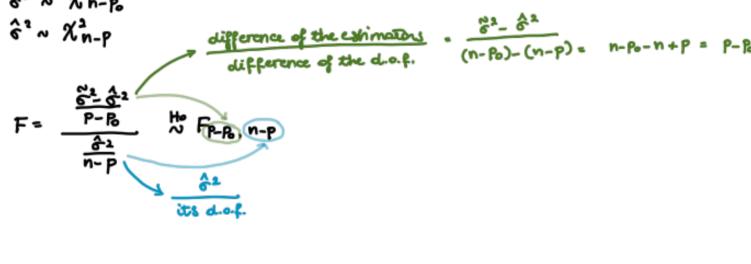

In particular, consider

$$F = \frac{\frac{8^2 - 6^2}{P - R}}{\frac{6^2}{h - P}} = \frac{\frac{8^2 - 6^2}{6} \cdot \frac{n - P}{P - R}}{\frac{6^2}{h - P}} = \frac{\frac{8^2 - 6^2}{E^* E} - E^* E}{\frac{E^* E}{h - P}} \cdot \frac{n - P}{P - R}$$

It holds F N Fp-Po, N-P

Reharks (1) the degrees of freedom

82 ~ Xn-B

are particular cases of this test.

(2) the test about an individual coefficient B; (test 1) and about the overall significance (test 2)

· TEST about a SINGLE PARAKETER BY Assume we one testing the significance of the last parameter Br.

(or simply sort the columns of X so that the last covariate is the one corresponding to the parameter of interest)

Testing Bp is equivalent to testing a model with B = P-1 covariates In this case we can perhition β and X as

$$\frac{\beta}{\beta} = \begin{bmatrix} \beta_1 \\ \vdots \\ \beta_{P-1} \\ \beta_P \end{bmatrix}$$

$$A = \begin{bmatrix} x_1 & \dots & x_{P-1} \\ x_P \end{bmatrix} \times \begin{bmatrix} x_1 & \dots & x_{P-1} \\ x_P \end{bmatrix}$$
Indeed $p_0 = p-1$ and the text becomes

$$F = \frac{\frac{\hat{\kappa}^2 - \hat{\sigma}^2}{1}}{\frac{\hat{\sigma}^2}{N - P}} \text{ Ho } F_{a, N - P}$$

$$F = (T_p)^2 \text{ with } T_p = \frac{\hat{\beta}_p - 0}{\sqrt{\hat{V}(\hat{\beta}_p)}} \text{ Ho } t_{n - P}$$

$$\text{recall: if } V \sim t_{m_1} \text{ then } V^2 \sim F_{a, m})$$

$$\text{if we consider } \beta = 1$$

if we consider B = 1

then
$$\beta = \begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_P \end{bmatrix}$$

How then β

the text is $F = \frac{\frac{6^2 - 6^4}{P-1}}{\frac{6^2}{N}} \stackrel{\text{Ho}}{\sim} F_{P-1}, n-p$

which is equivolent to the test on the coefficient
$$R^2$$
 (Ho: $R^2=0$ vs Hz: $R^2\neq 0$)

(3) Geometric interpretation of the text

Here, the voicebles $(j, \times_1, ..., \times_p)$ are n-dimensional vectors, with coordinates the observations on the n units.

exemple with 2 vouldbles (\$1,\$2)

The coroniates $(x_1,...,x_p)$ identify a subspace of dimension p_1 C(x). This subspace is defined by all linear combinations $\beta_1 \times 1 + ... + \beta_p \times p = \times \beta$.

The mean of \underline{Y} is $\underline{\mu} = \underline{X} \underline{P} = \underline{X} \underline{P}$ the mean of \underline{Y} belongs to $C(\underline{X})$.

Corrider again the representation of the model in an n-dimensional space.

The vector is in general will not belong to C(X): indeed we have seen that $\hat{\mu} = \hat{y}$ is the outhoponal projection of \hat{y} onto CCX).

What hoppers when we compose NESTED models?

C(x) is the subspace of \$1 \times 1 + \$1 \times 2 -> \frac{1}{2} is the vector of this space that minimizes the distance between y and x^{β} : $\hat{y} = \hat{\beta}_1 \times_1 + \hat{\beta}_2 \times_2$

Assume we want to test H_0 ; $\beta_2 = 0$ vs H_1 ; $\beta_1 \neq 0$

Under Ho, I am saying that $\tilde{y} = \tilde{\beta}_1 \times 1 \rightarrow \tilde{y}$ will belong to the subspece defined by a straight line (and not to the enrire peane) - This is a constrained estimate:

By is the value minimizing the distance between & and XB = Bx X1 Test: we look how for is \hat{y} to \hat{y} or, equivolently, $\tilde{\underline{e}}$ to \underline{e} i.e. <u>d = <u>e</u> - <u>e</u></u>

example with 2 covortates X1 and X2
